

# Linear Equations: Slope

*We explore the slope of lines.*

We observed that a constant rate of change between points produces a linear relationship, whose graph is a straight line. Such a constant rate of change has a special name, **slope**, and we'll explore slope in more depth here.

**Definition** When  $x$  and  $y$  are two variables where the rate of change between any two points is always the same, we call this common rate of change the **slope**. Since having a constant rate of change means the graph will be a straight line, its also called the **slope of the line**.

Considering the definition for **rate of change**, this means that when  $x$  and  $y$  are two variables where the rate of change between any two points is always the same, then you can calculate slope,  $m$ , by finding two distinct data points  $(x_1, y_1)$  and  $(x_2, y_2)$ , and calculating

$$m = \frac{\text{change in } y}{\text{change in } x} = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}$$

A slope is a rate of change. So if there are units for the horizontal and vertical variables, then there will be units for the slope. The slope will be measured in

$$\frac{\text{vertical units}}{\text{horizontal units}}$$

**Definition** If the slope is constant and nonzero, we say that there is a **linear relationship** between  $x$  and  $y$ . When the slope is 0, we say that  $y$  is **constant** with respect to  $x$ .

Here are some linear scenarios with different slopes. As you read each scenario, note how a slope is more meaningful with units.

- If a tree grows 2.5 feet every year, its rate of change in height is the same from year to year. So the height and time have a linear relationship where the slope is 2.5 ft/yr.
- If a company loses 2 million dollars every year, its rate of change in reserve funds is the same from year to year. So the company's reserve funds and

time have a linear relationship where the slope is -2 million dollars per year.

- If Sakura is an adult who has stopped growing, her rate of change in height is the same from year to year—it's zero. So the slope is 0 in/yr. Sakura's height is constant with respect to time.

**Remark** A useful phrase for remembering the definition of slope is “rise over run.” Here, “rise” refers to “change in  $y$ ”,  $\Delta y$ , and “run” refers to “change in  $x$ ”,  $\Delta x$ . Be careful though. As we have learned, the horizontal direction comes first in mathematics, followed by the vertical direction. The phrase “rise over run” reverses this. (It's a bit awkward to say, but the phrase “run under rise” puts the horizontal change first.)

**Example 1.** *On Dec. 31, Yara had only \$50 in her savings account. For the the new year, she resolved to deposit \$20 into her savings account each week, without withdrawing any money from the account.*

*Yara keeps her resolution, and her account balance increases steadily by \$20 each week. That's a constant rate of change, so her account balance and time have a linear relationship with slope of  $20 \frac{\text{dollars}}{\text{week}}$ .*

### Explanation

We can model the balance,  $y$ , in dollars, in Yara's savings account  $x$  weeks after she started making deposits with an equation. Since Yara started with \$50 and adds \$20 each week, then  $x$  weeks after she started making deposits,

$$y = 50 + 20x$$

where  $y$  is a dollar amount. Notice that the slope,

$$20 \frac{\text{dollars}}{\text{week}}$$

, serves as the multiplier for  $x$  weeks.

We can also consider Yara's savings using a table

	$x$ (weeks since Dec 31)	$y$ (savings account balance in dollars)	
	0	50	
+1 →	1	70	← +20
+1 →	2	90	← +20
+2 →	4	130	← +40
+3 →	7	190	← +60
+5 →	12	290	← +100

In first few rows of the table, we see that when the number of weeks  $x$  increases by 1, the balance  $y$  increases by 20. The row-to-row rate of change is

$$\frac{20 \text{ dollars}}{1 \text{ week}} = 20 \frac{\text{dollars}}{\text{week}},$$

the slope. In any table for a linear relationship, whenever  $x$  increases by 1 unit,  $y$  will increase by the slope.

In further rows, notice that as row-to-row change in  $x$  increases, row-to-row change in  $y$  increases proportionally to preserve the constant rate of change. Looking at the change in the last two rows of the table, we see  $x$  increases by 5 and  $y$  increases by 100, which gives a rate of change of

$$\frac{100 \text{ dollars}}{5 \text{ week}} = 20 \frac{\text{dollars}}{\text{week}},$$

the value of the slope again.

We can see this constant rate of change on the graph by drawing in **slope triangles** between points on the graph, showing the change in  $x$  as a horizontal distance and the change in  $y$  as a vertical distance.

## The Relationship Between Slope and Increase/Decrease

In a linear relationship, as the  $x$ -value increases (in other words as you read its graph from left to right):

- if the  $y$ -values increase (in other words, the line goes upward), its slope is positive.

**3 Acknowledgements:**Original source material, products with readable and accessible math content, and other information freely available at [pcc.edu/orcca](http://pcc.edu/orcca).

- if the  $y$ -values decrease (in other words, the line goes downward), its slope is negative.

- if the  $y$ -values don't change (in other words, the line is flat, or horizontal), its slope is 0.

## Finding the Slope by Two Given Points

Whenever you know two points on a line, you can find the slope of the line directly from the definition of slope.

**Example 2.** *Your neighbor planted a sapling from Portland Nursery in his front yard. Ever since, for several years now, it has been growing at a constant rate. By the end of the third year, the tree was 15 ft tall; by the end of the sixth year, the tree was 27 ft tall. What's the tree's rate of growth (i.e. the slope)?*

**Explanation** We could sketch a graph for this scenario, and include a slope triangle. If we did that, it would look like:

We don't actually need the picture, though, to find the slope. From the definition of slope, we have that

$$m = \frac{\text{change in } y}{\text{change in } x} = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}$$

We know that after 3 yr, the height is 15 ft. As an ordered pair, that information gives us the point (3,15) which we can label as  $(x_1, y_1)$ . Similarly, the background information tells us to consider (6,27), which we label as  $(x_2, y_2)$ . Here,  $x_1$  and  $y_1$  represent the first point's  $x$ -value and  $y$ -value, and  $x_2$  and  $y_2$  represent the second point's  $x$ -value and  $y$ -value.

Substituting in our values for  $x_1 = 3$ ,  $y_1 = 15$ ,  $x_2 = 6$ , and  $y_2 = 27$  into our definition of slope, we have

$$m = \frac{\text{change in } y}{\text{change in } x} = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1} = \frac{\Delta y}{\Delta x} = \frac{27 - 15}{6 - 3} = \frac{12\text{ft}}{3\text{yr}} = \boxed{4} \frac{\text{ft}}{\text{yr}}$$
